This is a single-author site, with no female authors. Viral and nonviral therapies for multiple sclerosis. The treatment options available for multiple sclerosis include pharmacological agents that are generally aimed at reduction of inflammatory neurodegeneration. However, most patients fail to achieve disease-free status. Over the last several years, a number of experimental immunotherapies have been explored, showing potential to treat patients who have not responded or are unable to tolerate current treatments. The most advanced of these are those based on regulatory T cells or immune modulatory antibodies. These are discussed here and their clinical potential is evaluated. Q: Effect of identifier in the declaration of an array constant I've encountered an interesting question that I would like to find the answer of, but I couldn't find anything about it. In the following snippet of code: void fun(int* Array) { // Do something } int main() { int array[] = {1,2,3,4}; fun(array); } which of the following two calls would behave differently: fun(array); fun(&array[0]); I understand the second call is an array of 4 pointers to int (similar to a pointer to pointer to int), while the first is an array of 4 int. Why is the compiler "aware" of the difference? A: The standard does not specify the semantics of accessing through an array constant. You could safely access it through a pointer or array (but not to another array constant). ISO/IEC 9899:2011 §6.4.4.2: An array type describes a contiguously allocated nonempty set of objects
